

CS1674: Homework 2

Due: 9/25/2018, 11:59pm

This assignment is worth 50 points.

The provided files can be found on CourseWeb.

Part I: Image Responses with Filters (10 points)

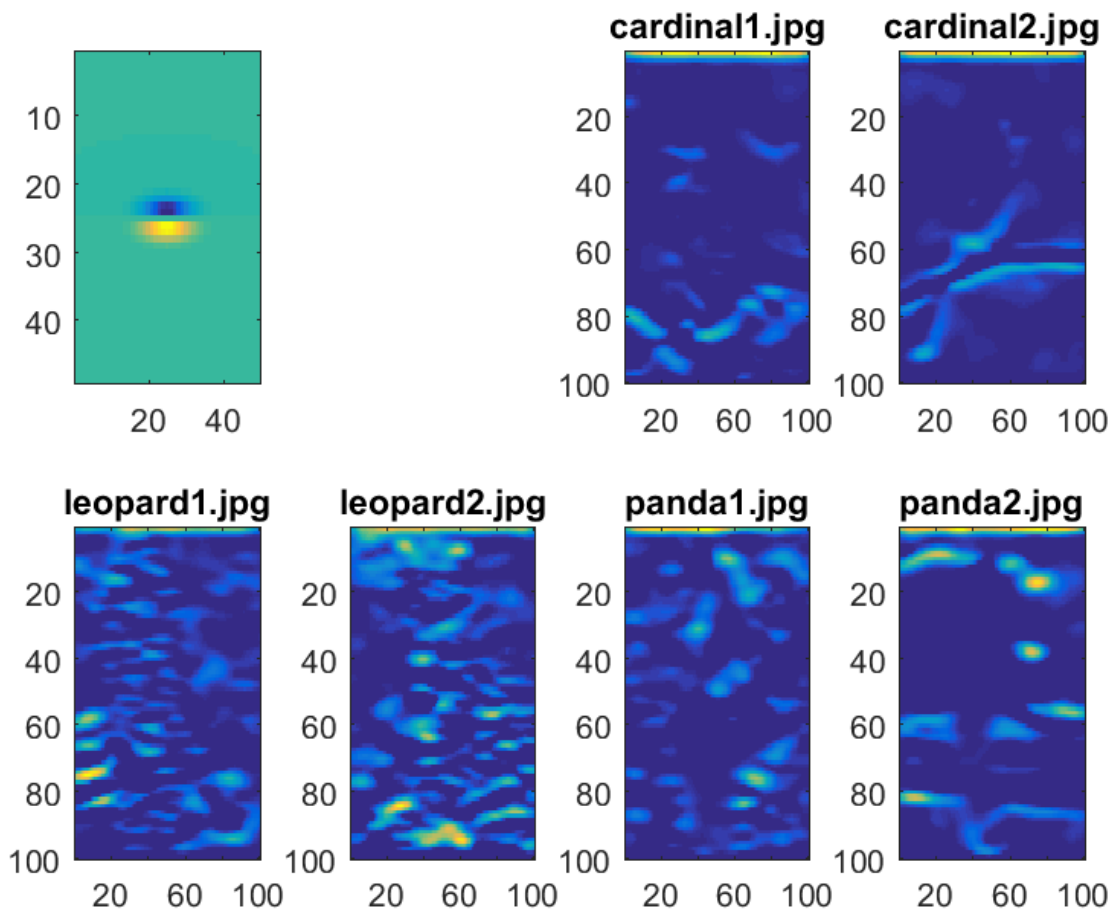

In this problem, you will measure the responses of images to different filters. For each image, you will compute the response of each image pixel to the filters from a "filter bank" as discussed in class. In a later assignment, you will use these responses to filters to compute image representations.

1. Download these images: [cardinal1](#), [cardinal2](#), [leopard1](#), [leopard2](#), [panda1](#), [panda2](#).
2. Download the script `makeLMfilters` from the [Leung-Malik filter bank](#) (also provided on CourseWeb), and run it (`F = makeLMfilters;`) to get a set of filters. Each filter $F(:, :, k)$ is of size 49x49, and there are 48 filters.
3. [4 pts] In a script `filter_responses.m`, use a cell array to store the list of filenames so you can loop over them (e.g. `filenames{i}`). Read in all images, convert them to grayscale, and resize them to the same square size (e.g. 100x100), so that the visual map of responses (filtering outputs) can be more comparable across images. Compute the cross-correlation of each image with each of the 48 filters using [imfilter](#).
4. [4 pts] For each filter, generate a 2x4 subplot showing the following subplot rows: (1) the filter and a blank subplot, (2) the responses to the cardinal images, (3) the responses to the leopard images, and (4) the responses to the panda images.
5. [2 pts] Choose and include in your submission (1) one filter where the responses for the same animal category are similar, while the responses for different animal categories are quite distinct; and (2) one filter where responses of different animals look fairly similar. Name the files `same_animal_similar.png` and `different_animals_similar.png`. See an example for one filter below.

Tips:

- You can use `saveas(gcf, strcat('responses_to_filter_', num2str(i), '.png'))`; to save your subplots, so you can later browse through them and pick interesting examples.
- You can also save images directly without displaying them, by turning the

visibility off using `set(0, 'DefaultFigureVisible', 'off');` near the beginning of your script. Make sure to turn it back on after this assignment!

Part II: Hybrid Images (10 points)

In this problem, you will create a hybrid image (which looks like one thing zoomed in and another zoomed out) like the one shown in class.

1. Download one pair of images:
 - [woman_happy](#) and [woman_neutral](#), or
 - [baby_happy](#) and [baby_weird](#).
2. [3 pts] In a script `hybrid_image.m`, read in the first image in the pair as `im1` and the second as `im2`. Convert both images to grayscale, and resize them to the same square size (e.g. 512x512).
3. [2 pts] Apply a Gaussian filter to both, using e.g. `imgaussfilt(im1, 10, 'FilterSize', 31)`. Save the results as `im1_blur`, `im2_blur`.
4. [2 pts] Obtain the detail image, by subtracting `im2_blur` from `im2`, and save the result as `im2_detail`.
5. [3 pts] Now add `im1_blur` and `im2_detail`, show the image, save it as

'hybrid.png', and include it with your submission. Play with scaling it up and down (by dragging the corner of the Matlab figure) to see the "hybrid" effect.

Part III: Content-Aware Image Resizing (30 points)

You will implement one part of the content-aware image resizing technique described in Shai Avidan and Ariel Shamir's SIGGRAPH 2007 paper, "Seam Carving for Content-Aware Image Resizing", available [here](#). First read through the paper, with emphasis on Section 3. Most functions will be provided for you, and some you will have to write. *The goal is to get more practice with Matlab, examine the performance of the method on different kinds of input images, and produce visually interesting results.* See some examples of my outputs and interesting results from previous times the course was taught, [here](#).

Here is the code you need to develop:

1. [5 points] Function `[energyImage, Ix, Iy] = energy_image(im)` - to compute the energy at each pixel using the magnitude of the x and y gradients.

Inputs:

- `im` should be a `nrows-x-ncols-x-3` matrix of class (datatype) `uint8`, e.g. the output of `imread` on a color image. However, you need to convert it to grayscale before computing the gradients, using `rgb2gray`.

Outputs:

- Each of the outputs `energyImage`, `Ix`, `Iy` should be 2D matrices of class `double`, each of size `nrows-x-ncols-x-1`.
- `Ix`, `Iy` are the gradients in the x and y directions, i.e. the dI/dx and dI/dy ; use two of the filters we discussed in class to compute them. Don't use Matlab's `imgradient` function but you are welcome to use `imfilter`.
- `energyImage` is computed similar to equation 1 in the paper, but using L2 norm: $\sqrt{(dI/dx)^2 + (dI/dy)^2}$.

2. [5 points] Function `displaySeam(im, seam, seamDirection)` - to display the selected type of seam on top of the input image.

Inputs:

- The input `im` should be the result of an `imread`.
- `seamDirection` should be the string 'HORIZONTAL' or 'VERTICAL'.
- `seam` should be the output of `find_optimal_vertical_seam` or `find_optimal_horizontal_seam` (which are provided for you).

Tips:

- To plot points on top of a displayed image in an existing figure, first use `hold on`; followed by `plot(...)`.
- The key challenge here will be figuring out in what order to give the arguments to the `plot` function calls. The first argument corresponds to the x axis, and the second to the y axis. A seam is a collection of points, and each point should be plotted at a particular point on the x axis and on the y axis. You will need to understand what the pixel stored at a particular index in a seam represents (i.e. where it came from), and it is helpful to think about what the lengths of the seams equal. Also note that when you plot things over an image, rows of the image correspond to the y axis, and columns to the x axis.

3. [5 pts] Function `[reducedColorImage] = reduceWidth(im, display_flag)` - to reduce the width of your image in a content-aware way. The function should call the `energy_image`, `cumulative_minimum_energy_map`, and `find_optimal_vertical_seam` functions.

Inputs:

- The function should take in a `nrows-x-ncols-x-3` matrix `im` of class `uint8`.
- If the `display_flag` is set to `true`, the function should display, in a `1x3` subplot, the following: (a) the energy image, (b) the cumulative energy image, (c) the optimal seam (using `displaySeam`).

Outputs:

- The output must be a 3D matrix `reducedColorImage`, of class `uint8`, which is the same as the input image but with its width reduced by one pixel.

Tips:

- The corresponding function `[reducedColorImage] = reduceHeight(im)` is provided for you; use it to see one possible way to implement the reduction in width.

4. [5 points] Function `[] = generate_results(filename, reduceAmt, reduceWhat)` - to run the functions you wrote, and the provided functions, on an image, and show the results. In your function, after reading in the image, you should call `reduceWidth` or `reduceHeight` as many times as needed to reduce the width/height by the requested amount, but should only set the display flag to `true` in the first iteration. You should also display, in a `1x3` subplot: (a)

the original image, (b) the final content-aware-reduced image, and (c) the content-agnostic reduction using a simple `imresize`. Label the figure with a `suptitle` indicating what was reduced, and by how many pixels. Label the subfigures with titles "original", "content-aware", "standard".

Inputs:

- `filename` is a character array (e.g. `'pittsburgh.png'`),
- `reduceAmt` is an integer which says by how many pixels to reduce the width/height, and
- `reduceWhat` is `'WIDTH'` or `'HEIGHT'`.

Required visual results:

5. [5 pts] Include the visual results of running `generate_results` on the provided [prague.jpg](#) and shrinking its height by 100 pixels. Also include the results of shrinking the width of the provided [mall.jpg](#) by 100 pixels. For both images, include:
 - the original image and the results of standard and content-aware reduction (saved as files `prague_height_reduced.png` and `mall_width_reduced.png`),
 - the energy and cumulative energy maps for the original image, and the first optimal seam (saved as files `prague_energy.png` and `mall_energy.png`).
6. [5 pts] Provide one interesting result on a different image of your choice. The goal is to form some perceptually pleasing outputs where the resizing better preserves content than a blind resizing would, or an example where the output looks unrealistic or has artifacts ("failure cases"). Be creative in the images you choose, and in the amount of combined vertical and horizontal carvings you apply. If you have a large image, try applying `imresize` first to resize the image to a small size, in order to make the computations faster and allow you to try more ways of transforming the image. Create a 1x3 subplot and display the following three: (a) the original image, (b) resizing using `imresize`, and (c) content-aware resizing in your submission. Use a title in your figure to say by how much you reduced the size, and in which direction. Name the file `interesting.png` and include it in your submission.

Provided functions:

- `M =`
`cumulative_minimum_energy_map(energyImage, seamDirection)`

- computes minimum cumulative energy. The input `energyImage` is a 2D matrix output by the `energy_image` function above, and the input `seamDirection` is 'HORIZONTAL' or 'VERTICAL'. The output is a 2D matrix of class `double`.
- `verticalSeam = find_optimal_vertical_seam(M)` and `horizontalSeam = find_optimal_horizontal_seam(M)` - compute the optimal vertical and horizontal seams. The input is the 2D matrix output by the function above, and the output is a vector containing the row indices (or column indices, respectively) of the pixels belonging to a horizontal (or vertical, respectively) seam. For a horizontal seam, you have as many seam points as you have image columns, i.e. one row index for each image column.
- `[reducedColorImage] = reduceHeight(im, display_flag)` - reduces the height of your image in a content-aware way (see description of `reduceWidth` above)

Submission: Please submit the following files:

- `filter_responses.m`
- `same_animal_similar.png` and `different_animals_similar.png`
- `hybrid_image.m`
- `hybrid.png`
- `energy_image.m`
- `displaySeam.m`
- `reduceWidth.m`
- `generate_results.m`
- `prague_height_reduced.png`, `mall_width_reduced.png`, `prague_energy.png`, and `mall_energy.png`
- `interesting.png`

Acknowledgement: Part I is partially based on an exercise by Kristen Grauman.
